Offshore Vessel Traffic

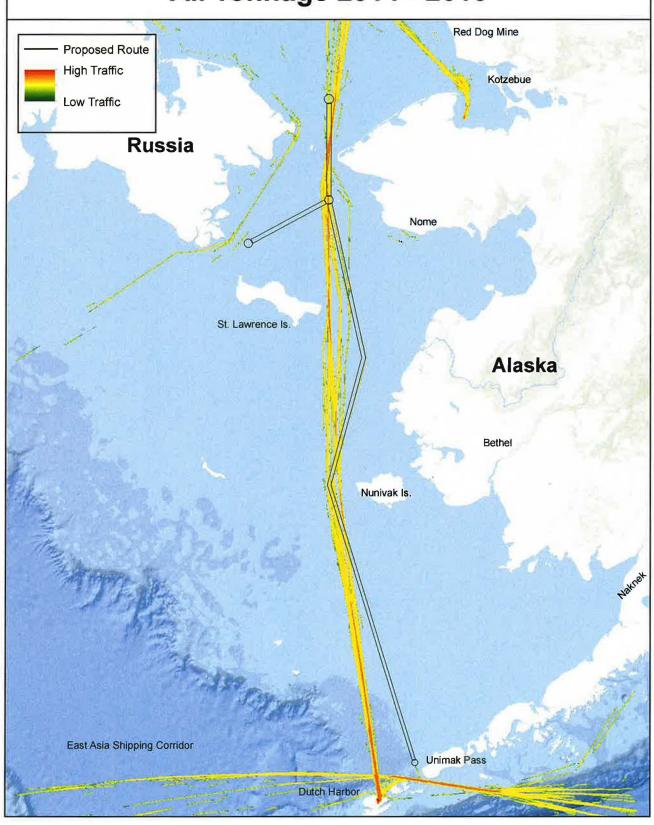

This category of traffic was added to analyze information on vessels participating in Outer Continental Shelf (OCS) exploratory drilling, which has recently led to an increase in transits of the Bering Strait. Offshore industry vessels operating within the Bering Sea region are predominantly destined for the Chukchi and Beaufort Seas and typically make a nonstop transit by the shortest route possible across the Bering Sea. This direct route involves transiting in close proximity to the east side of St. Lawrence Island, which is an environmentally sensitive area and punctuated with shoal water. Nearly all vessels bound for areas where OCS activity might occur in US Arctic waters would be well suited to follow the recommended route. This affords a vessel the opportunity to follow a well surveyed transit route, increase their distance from shore and avoid environmentally sensitive areas.

The proposed two-way route pass through several OSC lease sale areas. Currently there are no plans for additional OCS lease sales in Alaskan waters south of the Bering Strait, but lease sales have occurred previously in this area. In 1983, lease sales #57 and #70 offered tracts in the Norton Basin and St. George Basin, respectively. In 1988, Lease Sale #92 offered tracts in the North Aleutian Basin, which is located just to the east of the proposed two-way route. The Coast Guard finds it advantages to identify ship routing measures in advance of OCS development. Doing so aids in the screening process by identifying which specific tracts should be reserved from lease to meet the needs of navigation.

Research Vessels and Icebreaker Traffic

Research and Icebreaking vessels regularly operate in the Bering Sea and above the Bering Strait. Due to the nature of their work, these vessels have irregular traffic patterns that are highly variable. There are times however, when their transit does correlate with the proposed routing measures and they would be well suited to follow the recommended rout thereby allowing them to follow a well surveyed transit route, increase their distance from shore and avoid environmentally sensitive areas.

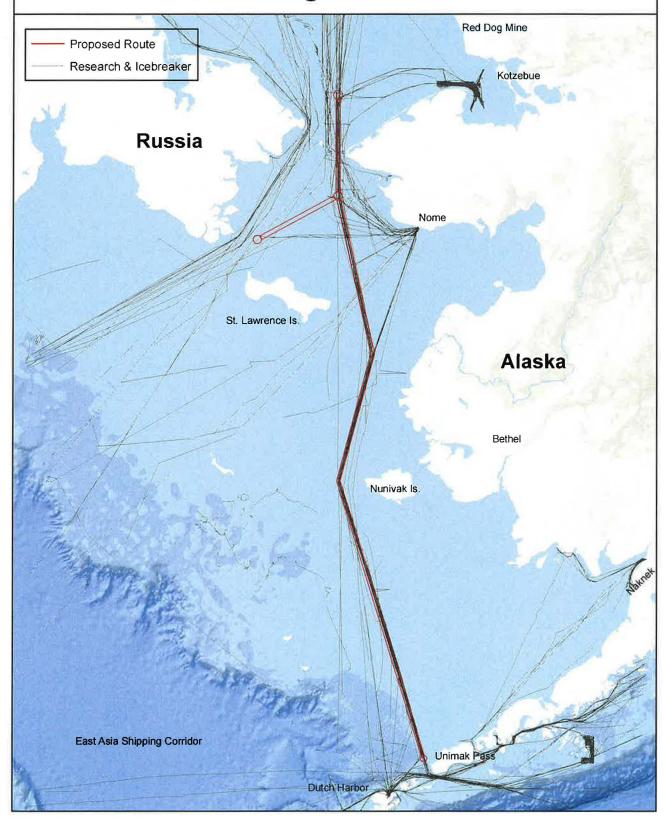

The heat track map indicates much more frequent use of the proposed two-way route by research vessels and icebreakers. This is due, in part, to vessels in this category actively gathering hydrographic survey data on the proposed route in 2014 and 2015.

Tug and Barge Traffic

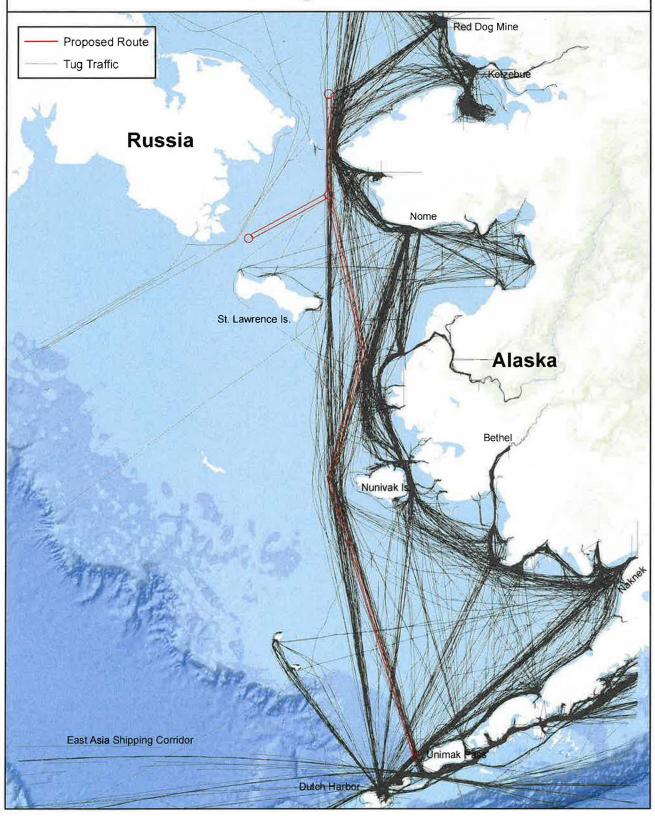

Tug vessel traffic operating in the Bering Sea region is predominately tug and barge services making cargo deliveries to coastal communities. Tank barges carrying petroleum products are captured under the tank vessel category. Consequently the typical tug vessel transit profile is involves coastal trade routes as opposed to transits through the central Bering Sea. These vessels are not expected to utilize the proposed route unless it is convenient for a tug's particular destination. There are, however, a few tug vessels that depart Dutch Harbor and transit continuously through the Bering Strait for operations in the Beaufort and Chukchi Sea's and Alaska's Northern Coast. Some of this tug traffic is transporting equipment and supplies for ongoing North Slope oil and gas exploration and production which is centered near Prudhoe Bay. This segment of tug/barge traffic could increase in the near future, triggered by additional on-shore oil & gas development as well as exploration and development of new prospects in waters managed by the State of Alaska. One recent find in Smith Bay is a good example of this. Smith Bay lies well to the west of Prudhoe Bay and is most easily accessed by water as opposed to existing onshore North Slope infrastructure. This traffic would be well suited to follow the recommended route which allows tugs bound for the North Slope to follow a well surveyed transit route, increase their distance from shore and avoid environmentally sensitive areas.

Miscellaneous Vessel Traffic

The miscellaneous vessel types that operate in the region are most heavily concentrated near the Aleutian Islands but occasionally transit across the Bering Sea and through the Bering Strait. Due to the nature of their work, these vessels have irregular traffic patterns that are highly variable. There are times however, when these transits do correlate with the proposed routing measures. In these cases, vessels would be well suited to follow the recommended two-way route which allows vessels to follow a well surveyed transit route, increase their distance from shore and avoid environmentally sensitive areas.

Vessel Traffic Less than 400GT (Excluding Fishing Vessels)

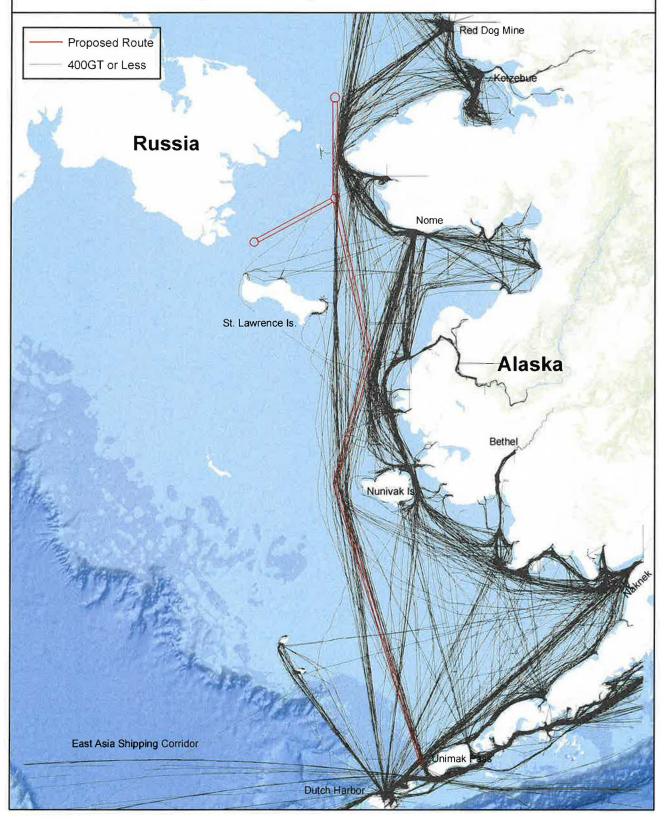

The next two map products are intended to illustrate the impact of applying ship routing measures to ships of a certain tonnage. A product of the recently completed Aleutian Island Risk Assessment was the installation of routing measures (Areas to be Avoided) for vessels transiting through passes in the Aleutian Island chain. These routing measures only apply to vessels greater than 400 Gross Tons (GT). As part of this study, the Coast Guard examined whether or not a similar "break point" based on vessel size would be appropriate for routing measures in other areas of the Bering Sea and Bering Strait. Investigation of AIS data validated 400GT as a reasonable "break point". The following analysis includes all vessel types (except fishing vessels) with a regulatory weight less than 400GT. Fishing industry vessels have been excluded from the dataset for clarity reasons, as the abundance of fishing vessels masks the transit trends of other vessels. The resulting profile for ships less than 400GT shows that a majority of these smaller vessels operating in the region are following near-coastal routes and thus will not likely follow the proposed routing measures.

Vessel Traffic 400GT and Over (Excluding Fishing Vessels)

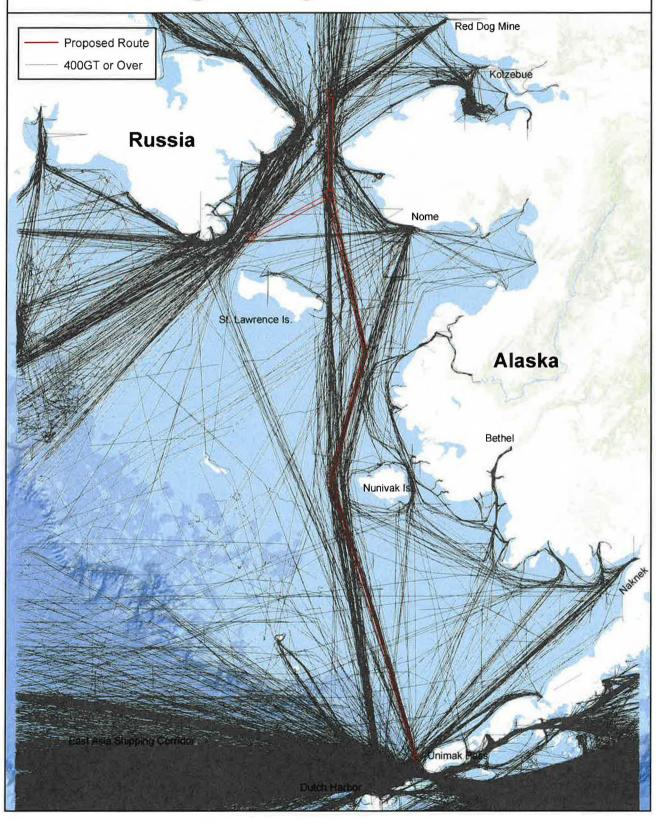

The following map product shows all vessel types with a regulatory weight of 400GT and over. As in the previous map product, fishing vessels have been excluded from the dataset for clarity reasons. The resulting profile shows that ships 400GT and greater are more likely to operate in the vicinity of the proposed routing measures, and thus more likely to follow the proposed routing measures and accrue the risk mitigation benefits of doing so.
